INVESTOR IN PEOPLE

The Patent Office  
Concept House  
Cardiff Road  
Newport  
South Wales

NP10 899 RECD 07 JAN 2005
WIPO PCT

**PRIORITY  
DOCUMENT**  
SUBMITTED OR TRANSMITTED IN  
COMPLIANCE WITH RULE 17.1(a) OR (b)

I, the undersigned, being an officer duly authorised in accordance with Section 74(1) and (4) of the Deregulation & Contracting Out Act 1994, to sign and issue certificates on behalf of the Comptroller-General, hereby certify that annexed hereto is a true copy of the documents as originally filed in connection with the patent application identified therein.

In accordance with the Patents (Companies Re-registration) Rules 1982, if a company named in this certificate and any accompanying documents has re-registered under the Companies Act 1980 with the same name as that with which it was registered immediately before re-registration save for the substitution as, or inclusion as, the last part of the name of the words "public limited company" or their equivalents in Welsh, references to the name of the company in this certificate and any accompanying documents shall be treated as references to the name with which it is so re-registered.

In accordance with the rules, the words "public limited company" may be replaced by p.l.c., plc, P.L.C. or PLC.

Re-registration under the Companies Act does not constitute a new legal entity but merely subjects the company to certain additional company law rules.

Signed

*Stephen Hordley*

**Warning**

After an application for a patent has been filed, the Comptroller of the Patent Office will consider whether publication or communication of the invention should be prohibited or restricted under Section 22 of the Patents Act 1977. You will be informed if it is necessary to prohibit or restrict your invention in this way. Furthermore, if you live in the United Kingdom, Section 23 of the Patents Act 1977 stops you from applying for a patent abroad without first getting written permission from the Patent Office unless an application has been filed at least 6 weeks beforehand in the United Kingdom for a patent for the same invention and either no direction prohibiting publication or communication has been given, or ~~any such direction has been revoked~~.

**Notes**

- If you need help to fill in this form or you have any questions, please contact the Patent Office on 08459 500505.
- Write your answers in capital letters using black ink or you may type them.
- If there is not enough space for all the relevant details on any part of this form, please continue on a separate sheet of paper and write "see continuation sheet" in the relevant part(s). Any continuation sheet should be attached to this form.
- If you have answered 'Yes' Patents Form 7/77 will need to be filed.
- Once you have filled in the form you must remember to sign and date it.
- For details of the fee and ways to pay please contact the Patent Office.

1 "Detection of Protein Interactions"

2

3 Field of the Invention

4

5 The present invention relates to a method of  
6 detecting interactions between macromolecules. In  
7 particular, but not exclusively, the invention  
8 relates to a method of detecting protein  
9 interactions using fluorescence.

10

11 Background to the Invention

12

13 Protein to protein interactions play a key role in  
14 many biological processes including the assembly of  
15 enzymes, protein homo/hetero-oligomers, regulation  
16 of intracellular transport, gene expression,  
17 receptor-ligand interactions, entry of pathogens  
18 into the cell and the action of small molecules or  
19 drugs.

20

1 Identification and characterisation of  
2 macromolecular interactions can be performed using  
3 co-immunoprecipitation from cell lysates and  
4 solubilised membranes. However, this technique  
5 requires specific antibodies for both capture and  
6 identification of proteins and may further require  
7 the use of detergent to disrupt interactions.

8  
9 More recently non-invasive techniques have been  
10 developed to determine protein to protein  
11 interactions.

12  
13 Such non-invasive techniques were pioneered by the  
14 yeast two hybrid method which is based on  
15 complementation of a split yeast nuclear  
16 transcription factor. The yeast two hybrid method  
17 utilises a mammalian bait protein connected to a  
18 yeast DNA-binding domain. This bait protein is used  
19 to determine which prey proteins are able to bind to  
20 the bait protein from a mixture of prey proteins.

21 The mammalian prey protein is connected to a yeast  
22 transcription activation domain. When the mammalian  
23 bait and prey proteins interact, the yeast DNA-  
24 binding and transcription activating domains are  
25 brought together. The DNA binding domain can bind  
26 to the yeast DNA and the transcription activating  
27 domain is then suitably located to trigger the  
28 expression of a reporter gene encoding an enzyme  
29 which in turn can catalyse the production of a  
30 coloured product within the yeast cells thus  
31 indicating a successful interaction of bait with  
32 prey.

1  
2 The use of yeast expression systems to identify  
3 mammalian protein-to-protein interaction suffers  
4 from a number of flaws. Certain post-translational  
5 modifications, that are normally critical to  
6 mammalian protein interactions, cannot be achieved  
7 by yeast cells. For example, tyrosine  
8 phosphorylation is key to many mammalian  
9 intracellular protein binding events involved in  
10 signal transduction. However, the yeast genome  
11 contains no tyrosine kinase genes so  
12 phosphotyrosine-dependent protein interactions  
13 cannot be accessed in yeast two hybrid studies.  
14  
15 Furthermore, in yeast two hybrid screening the  
16 protein-complex must be able to translocate to the  
17 nucleus to cause expression of the reporter gene or  
18 cause downstream events to trigger the expression of  
19 a reporter gene. Thus proteins that are excluded  
20 from the yeast nucleus will not be accessible to  
21 this screening method.  
22  
23 Further methods such as protein complementation and  
24 the split ubiquitin method utilise similar  
25 underlying concepts to the yeast two hybrid method  
26 in that the interaction of two proteins (a bait and  
27 prey protein) act to express a reporter protein, the  
28 reporter gene allowing the interaction event to be  
29 visualised as a detectable signal.  
30  
31 Such methods which utilise the expression of a  
32 reporter enzyme to produce a detectable signal

1 suffer from the disadvantage that the location of  
2 the protein complexes being detected cannot be  
3 accurately visualised in the cell.

4  
5 Recently the technique of fluorescence energy  
6 transfer (FRET) has been used to determine protein  
7 to protein interactions. In this technique the  
8 interaction of two fluorophores indicates their  
9 close spatial proximity. For protein to protein  
10 interaction monitoring the addition of an absorbing  
11 moiety to one protein partner is complemented by the  
12 addition of a second fluorescing moiety to the  
13 second binding partner. Provided the emission  
14 spectrum of the absorbing moiety overlaps the  
15 excitation spectrum of the fluorescing moiety and  
16 both moieties are within 100Å of each other FRET  
17 will occur. Mutations in the sequence of green  
18 fluorescent protein (GFP) from the jellyfish  
19 *Aequorea victoria* have been studied and shown to  
20 cause variations in the spectral emission of GFP  
21 giving rise to variants of GFP such as Yellow  
22 Fluorescent Protein (YFP), as well as cyan (CFP) and  
23 blue (BFP) fluorescing variants. This technique uses  
24 fluorescent energy transfer between these colour  
25 variants of GFP which are fused to interacting  
26 proteins to determine protein to protein  
27 interaction. Using this method, when the two GFP  
28 derived fluorophores are brought into close  
29 proximity, energy transfer between the fluorescent  
30 variants occurs and changes in fluorescence  
31 emissions are detected. Unfortunately, this method  
32 requires overexpression of the GFP fusion proteins

1 to allow quantification of the small changes in  
2 fluorescence. Related methods to FRET require the  
3 use of irreversible photobleaching (FRAP) or  
4 expensive instruments capable of measuring  
5 fluorescence lifetime imaging (FLIM).

6  
7 As a preliminary to the current experiments it was  
8 shown that green fluorescent protein can be  
9 engineered to add amino acid residues at particular  
10 regions in the GFP sequence whilst fluorescence is  
11 retained. Further, it has been shown in Hu, CD,  
12 Chinenov, Y. and Kerppola, T. K. (2002). *Mol. Cell.*  
13 9, 789-798 that using recombinant DNA technology  
14 specific Yellow Fluorescent Protein (YFP) fragments  
15 covalently fused to peptide sequences, which are  
16 capable of interacting with each other can  
17 reconstitute a fluorophore when the YFP fragments  
18 are brought together, such that the peptide  
19 sequences could interact.

20  
21 Further, it has recently been shown that  
22 fluorescence can be generated following the  
23 functional association of two separate fragments of  
24 the GFP molecule (hapto-GFPs) when driven by the  
25 interaction of a pair of proteins fused via a linker  
26 to the new C' and N' termini of the hapto-GFPs.  
27 (Ghosh et al, (2000); Hu et al, (2002).

28  
29 However, the above methods suffer from the  
30 disadvantage that functional association of  
31 fluorescent fragments is limited by the constraints  
32 of stereochemistry imposed on the fragments by the

1 bait and prey proteins' association. If the fusion  
2 termini of the interacting partners are widely  
3 separated, productive association of the haptoGFPs  
4 will not occur and no signal will be generated to  
5 indicate the interaction between the bait and prey  
6 peptides.

7

8 The present inventors have overcome a number of  
9 problems of the prior art.

10

11 Summary of the Invention

12

13 According to a first aspect of the present invention  
14 there is provided a protein interaction system said  
15 system comprising a first construct which encodes a

16 first fragment of fluorescent protein, a first bait

17 peptide and a linker portion encoding at least 5

18 amino acid residues interposed between the first

19 fragment and the bait peptide and a plurality of

20 second constructs encoding a second fragment of

21 fluorescent protein, a prey peptide and a linker

22 portion encoding at least 5 amino acid residues

23 interposed between the second fragment and the prey

24 peptide and on interaction of the bait and a prey

25 peptide the first and second fragments of the

26 fluorescent protein complement each other such that

27 functional association of the first and second

28 fragments promotes fluorescence, wherein at least

29 two of the prey proteins have different amino acid

30 sequences.

31

7

- 1 Preferably all the prey proteins have different
- 2 amino acid sequences.
- 3 Preferably the first and / or second construct
- 4 comprises a linker portion which encodes between 15
- 5 to 100 amino acid residues.
- 6
- 7 Preferably the linker of the first and / or second
- 8 construct is comprised of substantially hydrophillic
- 9 amino-acid residues.
- 10
- 11 More preferably the linker of the first and / or
- 12 second construct is comprised of multiples of a
- 13 pentapeptide sequence such as glycyl-glycyl-glycyl-
- 14 glycyl-serine.
- 15
- 16 More preferably the linker of the first and / or
- 17 second construct is greater than 20 amino acids,
- 18 more preferably greater than 25 amino acids, more
- 19 preferably greater than 30 amino acids, more
- 20 preferably greater than 35 amino acids, even more
- 21 preferably greater than 40 amino acids, even more
- 22 preferably greater than 50 amino acids and yet more
- 23 preferably greater than 55 amino acids in length.
- 24
- 25 Preferably, the linker of the first and / or second
- 26 construct encodes up to 60 amino acids.
- 27
- 28 Where the peptides joined to the linkers are rod
- 29 like structures and the peptides interact with each
- 30 other with favourable topology of interaction, ie
- 31 the peptides interact such that the fragments of
- 32 fluorescent protein are brought into close proximity

1 with each other, short linker lengths are sufficient  
2 to allow screening for interaction partners. For  
3 example, short linkers could be used to screen a  
4 library of DNA binding proteins which from previous  
5 studies are known to be rod like in structure.

6  
7 However, linker lengths between 15 to 100 amino  
8 acids are advantageous over shorter linker lengths  
9 as they allow bulkier peptides being tested for  
10 interaction to be conjoined to the first and second  
11 fragments of the fluorescent protein without the  
12 peptides being tested placing constraints on the  
13 functional association of the fluorescent proteins  
14 due to stereochemical hindrance. Such longer  
15 linkers are also advantageous to study small peptide  
16 pairs that have an unfavourable topology of  
17 interaction such as is found in an anti-parallel  
18 complex (hapto-GFP- $N^1 \rightarrow C^1$ :binding to  $C^2 \rightarrow N^2$ -hapto-  
19 GFP) i.e. functional association of the interacting  
20 peptides causes the fluorescent fragments to be  
21 orientated such that they are directed away from  
22 each other in space.

23  
24 Any fluorescent protein may be used in the  
25 invention. However, in a preferred embodiment the  
26 fragments of fluorescent protein are fragments of  
27 green fluorescent protein, mutants or variants  
28 thereof.

29  
30 More preferably the fluorescent protein is the  
31 humanised form of a fluorescent protein, e.g.

1 Enhanced Green Fluorescent Protein (EGFP) or a  
2 variant thereof.

3

4 Variants include peptides in which individual amino  
5 acids are substituted by other amino acids which are  
6 closely related as understood in the art, for  
7 example, substitution of one hydrophobic residue  
8 such as isoleucine, valine, leucine or methionine  
9 for another, or the substitution of one polar  
10 residue for another, such as arginine for lysine,  
11 glutamic for aspartic acid or glutamine for  
12 asparagine.

13

14 In a humanised nucleotide sequence one or more of  
15 the codons in the sequence are altered such that for  
16 the amino acid being encoded, the codon used is that  
17 which most frequently appears in humans. This is  
18 advantageous as the humanised fluorescent protein  
19 construct e.g. (EGFP) has maximised expression  
20 levels and rate of fluorophore formation in mammalian  
21 cells. This makes detection of fluorescence,  
22 produced by fragments of fluorescent proteins  
23 (fluorogenic fragments) which functionally associate  
24 with each other, easier to determine.

25

26 In a second aspect, there is provided a library of  
27 constructs encoding a fragment of fluorescent  
28 protein, a peptide and a linker portion of at least  
29 5 amino acids interposed between said fragment and  
30 peptide wherein said fragment of fluorescent protein  
31 is capable of functional association with a  
32 complementary fragment of fluorescent protein such

1 that on functional association of said fragments  
2 fluorescence is enabled wherein the library of  
3 constructs encodes a plurality of different  
4 peptides.

5  
6 Each member of the library encodes or provides a  
7 different peptide fused to a fragment of fluorescent  
8 protein via a linker. The peptides can be small  
9 peptides of differing amino acid sequence, for  
10 example nonomers, comprising different amino acid  
11 compositions or the same overall composition but  
12 with the amino acids present in a different order.  
13 Alternatively the peptides may be full size proteins  
14 obtained from a cDNA library.

15  
16 Preferably the constructs of the library comprise a  
17 linker portion which encodes between 15 to 100 amino  
18 acid residues.

19  
20 Preferably the linker is comprised of substantially  
21 hydrophillic amino-acid residues.

22  
23 More preferably the linker is comprised of multiples  
24 of a pentapeptide sequence such as glycyl-glycyl-  
25 glycyl-glycyl-serine.

26  
27 More preferably the linker portion is greater than  
28 20 amino acids, more preferably greater than 25  
29 amino acids, more preferably greater than 30 amino  
30 acids, more preferably greater than 35 amino acids,  
31 even more preferably greater than 40 amino acids,  
32 even more preferably greater than 50 amino acids and

11

1 yet more preferably greater than 55 amino acids in  
2 length.

3

4 Preferably, the linker encodes up to 60 amino acids.

5

6 The invention further provides in a third aspect a  
7 library of polypeptides, each polypeptide comprising  
8 a fragment of fluorescent protein, a peptide and a  
9 linker portion of at least 5 amino acid residues  
10 interposed between the fragment and the peptide of  
11 the polypeptide.

12

13 Unless the context demands otherwise, the term  
14 peptide, polypeptide and protein are used  
15 interchangeably to refer to amino acids in which the  
16 amino acid residues are linked by covalent peptide  
17 bonds or alternatively (where post-translational  
18 processing has removed an internal segment) by  
19 covalent di-sulphide bonds, etc. The amino acid  
20 chains can be of any length and comprise at least  
21 two amino acids, they can include domains of  
22 proteins or full-length proteins. Unless otherwise  
23 stated the terms, peptide, polypeptide and protein  
24 also encompass various modified forms thereof,  
25 including but not limited to glycosylated forms,  
26 phosphorylated forms etc.

27

28 Polypeptides may be made synthetically or  
29 recombinantly using techniques which are widely  
30 available in the art.

31

32

1 In preferred embodiments, the fragments of  
2 fluorescent protein (fluorogenic fragments) are  
3 generatable through the introduction of a split  
4 point between the amino acids at positions 157 and  
5 158, or (in a second embodiment) between the amino  
6 acids at positions 172 and 173 of the humanised form  
7 of Green Fluorescent Protein (SEQ ID NO 1).

8

9 SEQ ID NO 1 - EGFP (Clontech Inc.) [Genbank  
10 Accession number gb:AAB02574 gi 1377912]:

11 1 mvskgeelft gvpilveld gdvngkhkfsv sgegegdaty  
12 41 gkltlkfict tgklvpwpt lvtlttygvq cfsrypdkmk  
13 81 qhdfkfsamp egyvqertif fkddgnyktr aevkfegdtl  
14 121 vnriekgid fkedgnilgh kleynynshn vyimadkqkn  
15 161 gikvnfkirh niedgsvqla dhyqqntpig dgpvllpdnh  
16 201 ylstqsalsk dpnekrdhmv llefvttaagi tlgmdelyk

17

18 The fluorogenic fragments generated by the  
19 introduction of a split point between the amino acid  
20 residues at positions 157 and 158, or between amino  
21 acid residues at positions 172 and 173, result in  
22 the production of hapto-EGFP<sup>1/157</sup> and hapto-EGFP<sup>158/239</sup>,  
23 or hapto-EGFP<sup>1/172</sup> and hapto-EGFP<sup>173/239</sup>, respectively.

24

25 Alternative split points are between residues 23/24,  
26 38/39, 50/51, 76/77, 89/90, 102/103, 116/117,  
27 132/133, 142/143, 190/191, 211/212, 214/215 of EGFP.

28

29 Thus in preferred embodiments, the fragment  
30 comprises a fluorogenic fragment of amino acid  
31 residues 1 to 23, 1 to 38, 1 to 50, 1 to 76, 1 to  
32 89, 1 to 102, 1 to 116, 1 to 132, 1 to 142, 1 to

1 157, 1 to 172, 1 to 190, 1 to 211, 1 to 214, 24 to  
2 239, 39 to 239, 51 to 239, 77 to 239, 90 to 239, 103  
3 to 239, 117 to 239, 133 to 239, 143 to 239, 158 to  
4 239, 173 to 239, 191 to 239, 212 to 239, or 215 to  
5 239 of EGFP.

6

7 In one preferred embodiment a library of  
8 polypeptides according to a further aspect of the  
9 invention is provided wherein each member of the  
10 library has a different peptide sequence fused to  
11 the fragment of fluorescent protein via the linker  
12 region.

13

14 A bait peptide is a sequence of two or more amino  
15 acids, at least one domain of a protein or a full  
16 length protein.

17

18 A prey peptide is a sequence of two or more amino  
19 acids, at least one domain of a protein or a full  
20 length protein.

21

22 The term interaction or interacting as used herein  
23 means that two entities, for example, distinct  
24 peptides, domains of proteins or complete proteins,  
25 exhibit sufficient physical affinity to each other  
26 so as to bring the two interacting entities  
27 physically close to each other. An extreme case of  
28 interaction is the formation of a chemical bond that  
29 results in continual, stable proximity of the two  
30 entities. Interactions that are based solely on  
31 physical affinities, although usually more dynamic  
32 than chemically bonding interactions, can be equally

1 effective at co-localising independent entities.  
2 Physical affinities include, but are not limited to,  
3 for example electrical charge differences,  
4 hydrophobicity, hydrogen bonds, van der Waals force,  
5 ionic force, covalent linkages, and combinations  
6 thereof. The interacting entities may interact  
7 transiently or permanently. Interaction may be  
8 reversible or irreversible. In any event it is in  
9 contrast to and distinguishable from natural random  
10 movement of two entities. Examples of interactions  
11 include specific interactions between antigen and  
12 antibody, ligand and receptor etc.

13  
14 In a fourth aspect of the invention there is  
15 provided a protein interaction monitoring system,  
16 said system comprising a first polypeptide  
17 comprising a first fragment of fluorescent protein,  
18 a bait peptide and a linker portion of at least 5  
19 amino acid residues interposed between the first  
20 fragment and the bait peptide and a plurality of  
21 second polypeptides comprising a second fragment of  
22 fluorescent protein, a prey peptide and a linker  
23 portion of at least 5 amino acid residues interposed  
24 between the second fragment and the prey peptide and  
25 on interaction of the bait and a prey peptide the  
26 first and second fragments of the fluorescent  
27 protein complement each other such that functional  
28 association of the first and second fragments  
29 promotes fluorescence, wherein at least two of the  
30 prey proteins have different amino acid sequences.

31

15

1 Preferably the linker portion of the first and / or  
2 second polypeptide comprises between 15 to 100 amino  
3 acid residues.

4

5 Preferably the linker of the first and / or second  
6 polypeptide is comprised of substantially  
7 hydrophillic amino-acid residues.

8

9 More preferably the linker of the first and / or  
10 second polypeptide is comprised of multiples of a  
11 pentapeptide sequence such as glycyl-glycyl-glycyl-  
12 glycyl-serine.

13

14 More preferably the linker portion of the first and  
15 / or second polypeptide is greater than 20 amino  
16 acids, more preferably greater than 25 amino acids,  
17 more preferably greater than 30 amino acids, more  
18 preferably greater than 35 amino acids, even more  
19 preferably greater than 40 amino acids, even more  
20 preferably greater than 50 amino acids and yet more  
21 preferably greater than 55 amino acids in length.

22

23 Preferably, the linker of the first and / or second  
24 polypeptide comprises up to 60 amino acids.

25

26 According to a fifth aspect of the present  
27 invention there is provided an assay method to  
28 determine peptide to peptide interactions comprising  
29 the steps of:

30

31 providing a first construct, said construct  
32 encoding a first fragment of fluorescent

1 protein, a first bait peptide and a linker  
2 portion of at least 5 amino acid residues  
3 interposed between the first fragment and the  
4 bait peptide;

5  
6 providing a plurality of second constructs said  
7 constructs encoding a second complementary  
8 fragment of fluorescent protein, a prey peptide  
9 and a linker portion of at least 5 amino acids  
10 interposed between the second fragment and the  
11 prey peptide wherein at least two constructs  
12 encode different prey proteins;

13  
14 expressing both constructs in the same cell;  
15 and

16  
17 detecting fluorescence produced in the cell.

18  
19 Preferably all the second constructs encode  
20 different prey proteins.

21  
22 Preferably the first and / or second construct  
23 comprises a linker portion which encodes between 15  
24 to 100 amino acid residues.

25  
26 Preferably the first and / or second linker is  
27 comprised of substantially hydrophillic amino-acid  
28 residues.

29  
30 More preferably the first and / or second linker  
31 encodes multiples of a pentapeptide sequence such as  
32 glycyl-glycyl-glycyl-glycyl-serine.

17

1

2 More preferably the linker of the first and / or  
3 second construct is greater than 20 amino acids,  
4 more preferably greater than 25 amino acids, more  
5 preferably greater than 30 amino acids, more  
6 preferably greater than 35 amino acids, even more  
7 preferably greater than 40 amino acids, even more  
8 preferably greater than 50 amino acids and yet more  
9 preferably greater than 55 amino acids in length.

10

11 Preferably, the linker of the first and / or second  
12 construct encodes up to 60 amino acids.

13

14 In an embodiment of the assay the fluorescence  
15 detected may be quantitatively determined such that  
16 fluorescence produced by different cells or under  
17 different conditions can be compared.

18

19 In one embodiment of the assay, the second construct  
20 is provided as a member of a library of second  
21 constructs wherein each member of the library  
22 encodes a different prey peptide wherein at least  
23 one second construct member of the library is  
24 expressed in the same cell as the first construct  
25 encoding the bait protein.

26

27 The assay can therefore be used to screen an  
28 expression library to determine those peptides which  
29 bind to a bait peptide.

30

31 There is also provided an assay to determine peptide  
32 to peptide interactions comprising the steps of:

1  
2 providing a first polypeptide comprising a  
3 first fragment of fluorescent protein, a first  
4 bait peptide and a linker portion of at least 5  
5 amino acid residues interposed between the  
6 first fragment and the bait peptide;

7  
8 providing a plurality of second polypeptides  
9 comprising a second fragment of fluorescent  
10 protein which is complementary to the first  
11 fragment of fluorescent protein, a prey peptide  
12 and a linker portion of at least 5 amino acids  
13 interposed between the second fragment and the  
14 prey peptide wherein at least two second  
15 polypeptides encode different prey proteins;

16  
17 mixing the first polypeptide and second  
18 polypeptide together; and

19  
20 detecting whether fluorescence is produced.

21  
22 Preferably the first and / or second polypeptide  
23 linker portion comprises between 15 to 100 amino  
24 acid residues.

25  
26 Preferably the first and / or second polypeptide  
27 linker is comprised of substantially hydrophillic  
28 amino-acid residues.

29  
30 More preferably the first and / or second  
31 polypeptide linker is comprised of multiples of a

1 pentapeptide sequence such as glycyl-glycyl-glycyl-  
2 glycyl-serine.

3

4 More preferably the first and / or second  
5 polypeptide linker portion is greater than 20 amino  
6 acids, more preferably greater than 25 amino acids,  
7 more preferably greater than 30 amino acids, more  
8 preferably greater than 35 amino acids, even more  
9 preferably greater than 40 amino acids, even more  
10 preferably greater than 50 amino acids and yet more  
11 preferably greater than 55 amino acids in length.

12

13 Preferably, the first and / or second polypeptide  
14 linker comprises up to 60 amino acids.

15

16 As detailed above the detected fluorescence can be  
17 quantitatively measured.

18

19 In a particular example the assay method is  
20 performed in vitro.

21

22 The assay method may further comprise the step of  
23 determining the location of the fluorescence in the  
24 cell. This is advantageous as it provides details  
25 of not only if a protein to protein interaction is  
26 occurring, but the location in the cell the  
27 interaction is taking place, for example at the  
28 membrane, in the cytoplasm, or in the nucleus.

29

30 In addition, the assay method may further comprise  
31 the step of isolating the bait and / or prey peptide  
32 encoded from the cell in which fluorescence has

1 resulted, for example isolating a cell using a  
2 fluorescence activated cell sorting machine then  
3 isolating and sequencing the interacting peptides.  
4 The sequenced peptides can then be compared with  
5 sequences (full length or partial) in a data bank so  
6 as to identify or characterise the interacting  
7 peptide isolated from the cell.

8

9 ~~The sequences of the interacting peptides may~~  
10 alternatively be inferred by cloning selected  
11 fluorescent cells and subjecting the cloned cells to  
12 PCR amplification and DNA sequencing. These  
13 sequences can then be cloned into expression vectors  
14 and the protein expressed and purified. The  
15 purified protein can be further studied or used for  
16 example in research.

17

18 In one embodiment, the assay method may further  
19 comprise the process of determining the subcellular  
20 dynamics of the peptide interactions visualised by  
21 fluorescence observations of living cells to enable  
22 spatio-temporal studies of peptide interactions  
23 throughout all parts of the cell cycle.

24

25 In a sixth aspect, which enables spatio-temporal  
26 studies, the invention provides an assay which  
27 comprises the steps of providing a first construct  
28 encoding a polypeptide comprising a first fragment  
29 of fluorescent protein, a first bait peptide and a  
30 linker portion of at least 5 amino acid residues  
31 interposed between the first fluorogenic fragment  
32 and the first bait peptide:

21

1  
2 providing a second construct encoding a  
3 polypeptide comprising a second fragment of  
4 fluorescent protein which is complementary to  
5 said first fluorescent fragment, a second prey  
6 peptide and a linker portion interposed between  
7 the second fluorogenic fragment and the second  
8 prey peptide;  
9  
10 causing the expression of both constructs  
11 within the same living cell; and  
12  
13 and observing the level of fluorescence  
14 produced and its subcellular location in the  
15 cell at a range of time points following co-  
16 expression of both constructs.  
17  
18 Preferably the first and / or second construct  
19 comprises a linker portion which encodes between 15  
20 to 100 amino acid residues.  
21  
22 Preferably the linker of the first and / or second  
23 construct is comprised of substantially hydrophillic  
24 amino-acid residues.  
25  
26 More preferably the linker of the first and / or  
27 second construct is comprised of multiples of a  
28 pentapeptide sequence such as glycyl-glycyl-glycyl-  
29 glycyl-serine.  
30  
31 More preferably the linker of the first and / or  
32 second construct is greater than 20 amino acids,

## 22

1 more preferably greater than 25 amino acids, more  
2 preferably greater than 30 amino acids, more  
3 preferably greater than 35 amino acids, even more  
4 preferably greater than 40 amino acids, even more  
5 preferably greater than 50 amino acids and yet more  
6 preferably greater than 55 amino acids in length.

7

8 Preferably, the linker of the first and / or second

9 construct encodes up to 60 amino acids;

10

11 In a seventh aspect, there is provided an assay for  
12 estimating the maximum possible separation of the  
13 fusion termini of the interacting peptides:

14

15 providing a first construct encoding a first  
16 fragment of fluorescent protein, a first bait  
17 peptide and a linker portion of at least 5  
18 amino acid residues interposed between the  
19 first fragment and the bait peptide;

20

21 providing a second construct encoding a second  
22 fragment of fluorescent protein which is  
23 complementary to said first fluorescent  
24 fragment, a prey peptide and a library of  
25 linkers of lengths ranging from 5 to 100 amino  
26 acids;

27

28 expressing both constructs in the same cell  
29 following co-transfection of a large population  
30 of cells with both constructs;

31

1 measuring fluorescence produced in the cell,  
2 selection of those cells with higher  
3 fluorescence, using either a fluorescence  
4 activated cell sorting machine or alternatively  
5 by employing laser microdissection; and  
6

7 clonally amplifying these fluorescent cells,  
8 and sequencing the region of a large sample of  
9 the constructs encoding the linkers and  
10 determining the length of the linkers.  
11

12 Preferably the linkers of the first and / or second  
13 construct are comprised of flexible pentapeptide  
14 sequences.  
15

16 Preferably the pentapeptide is comprised of  
17 substantially hydrophillic amino-acid residues.  
18 More preferably the pentapeptide is a sequence such  
19 as glycyl-glycyl-glycyl-glycyl-serine.  
20

21 Preferably the number of peptapeptide sequences in  
22 the linker is determined by sequencing.  
23

24 Preferably the linker of the first and / or second  
25 construct length is between 10 to 100 amino acids.

26 Alternatively the linker can be between 15 to 100  
27 amino acids in length. In a yet further alternative

28 the linker can be 20 to 100 amino acids in length.

29 As a further alternative the linker can be 30 to 100  
30 amino acids in length.  
31

1 A distribution of occurrence of linker lengths will  
2 be obtained in the fluorescent cells selected, with  
3 a sharp cutoff at the lower limit reflecting the  
4 minimum linker length capable of spanning the  
5 separation of the fusion termini of the interacting  
6 peptides and thus allowing productive association of  
7 the fluorogenic fragments. A maximum value for this  
8 distance may be evaluated in Ångstroms on the basis  
9 that each amino acid residue contributes 3.7Å to the  
10 length of each linker in an extended backbone  
11 conformation.

12  
13 Further assay methods of the present invention may  
14 be used to detect the interactions of three or more  
15 agents in a trimeric or higher order complex.

16  
17 In one example, three fluorescent fragments may  
18 provided by introducing two split points as  
19 discussed above into the fluorescent protein, each  
20 fragment being fused to a peptide. On interaction  
21 of the peptides the three or more fluorescent  
22 fragments are brought together such that they can  
23 functionally associate and generate a fluorescent  
24 signal capable of being detected.

25  
26 In another ~~example~~ one or more of the three  
27 fluorescent fragments can be fused to a test agent  
28 ~~such as a small molecule, such as a metal ion.~~ In  
29 this manner, protein interactions which require the  
30 participation of additional test agents, such as  
31 small molecules can be detected.

32

1 Modulation of the interaction between peptides may  
2 be a desirable outcome in the treatment of certain  
3 clinical conditions, or as a research tool to study  
4 peptide to peptide interactions. For example,  
5 modulation of protein to protein interactions may  
6 facilitate the task of determining the steps of  
7 complex pathways by the provision of means to  
8 promote or inhibit a specific interaction, allowing  
9 the effects of other proteins to be studied in  
10 better detail.

11  
12 Many protein to protein interactions require the  
13 participation of small molecules or peptides. Such  
14 a requirement can be determined by simply adding  
15 small molecule ligands or the peptides to the  
16 components of the assay to determine if these  
17 modulate protein to protein interaction as measured  
18 by an alteration in fluorescent signal.

19  
20 Thus in an eighth aspect there is provided an assay  
21 for determining whether a candidate agent modulates  
22 protein to protein interactions comprising the  
23 steps:

24

25 providing a first construct encoding a first  
26 fragment of fluorescent protein, a first bait  
27 peptide and a linker portion of at least 5  
28 amino acid residues interposed between the  
29 first fragment and the bait peptide;

30

31 providing a second construct encoding a second  
32 fragment of fluorescent protein which is

1 complementary to said first fluorescent  
2 fragment, a prey peptide and a linker portion  
3 of at least 5 amino-acids interposed between  
4 the second fragment and the prey peptide;

5  
6 providing a putative modulating agent;

7  
8 expressing both constructs in the same cell;

9 and

10  
11 measuring fluorescence produced in the cell in  
12 the presence and absence of said putative  
13 modulating agent

14  
15 wherein a reduction in fluorescence in the  
16 presence of said modulating agent compared to  
17 fluorescence in the absence of said candidate  
18 modulating agent is indicative of inhibition of  
19 complex formation by the modulating agent and  
20 an increase in fluorescence is indicative of  
21 enhancement of complex formation by the  
22 modulating agent.

23

24 Preferably the linker of the first and / or second  
25 construct comprises a linker portion which encodes  
26 between 15 to 100 amino acid residues.

27

28 Preferably the linker of the first and / or second  
29 construct is comprised of substantially hydrophillic  
30 amino-acid residues.

31

27

1 More preferably the linker of the first and / or  
2 second construct is comprised of multiples of a  
3 pentapeptide sequence such as glycyl-glycyl-glycyl-  
4 glycyl-serine.

5

6 More preferably the linker of the first and / or  
7 second construct is greater than 20 amino acids,  
8 more preferably greater than 25 amino acids, more

9 preferably greater than 30 amino acids, more

10 preferably greater than 35 amino acids, even more

11 preferably greater than 40 amino acids, even more

12 preferably greater than 50 amino acids and yet more

13 preferably greater than 55 amino acids in length.

14

15 Preferably, the linker of the first and / or second  
16 construct encodes up to 60 amino acids.

17

18 In a ninth aspect there is provided an assay for  
19 determining whether a candidate agent modulates  
20 protein to protein interactions comprising the  
21 steps:

22

23 providing a first polypeptide comprising  
24 a first fragment of fluorescent protein, a bait  
25 peptide and a linker portion of at least 5  
26 amino acid residues interposed between the  
27 first fragment and the bait peptide;

28

29 providing a second polypeptide comprising a  
30 second fragment of fluorescent protein which is  
31 complementary to said first fluorescent  
32 fragment, a prey peptide and a linker portion

1 of at least 5 amino-acids interposed between  
2 the second fragment and the prey peptide;  
3  
4 providing a putative modulating agent; and  
5  
6 measuring fluorescence produced in the presence  
7 and absence of said putative modulating agent  
8

9 wherein a reduction in fluorescence in the  
10 presence of said modulating agent compared to  
11 fluorescence in the absence of said candidate  
12 modulating agent is indicative of inhibition of  
13 complex formation by the modulating agent and  
14 an increase in fluorescence is indicative of  
15 enhancement of complex formation by the  
16 modulating agent.

17  
18 Preferably the linker of the first and / or second  
19 polypeptide comprises between 15 to 100 amino acid  
20 residues.

21  
22 Preferably the linker of the first and / or second  
23 polypeptide is comprised of substantially  
24 hydrophillic amino-acid residues.

25  
26 More preferably the linker of the first and / or  
27 second polypeptide is comprised of multiples of a  
28 pentapeptide sequence such as glycyl-glycyl-glycyl-  
29 glycyl-serine.

30  
31 More preferably the linker of the first and / or  
32 second polypeptide is greater than 20 amino acids,

1 more preferably greater than 25 amino acids, more  
2 preferably greater than 30 amino acids, more  
3 preferably greater than 35 amino acids, even more  
4 preferably greater than 40 amino acids, even more  
5 preferably greater than 50 amino acids and yet more  
6 preferably greater than 55 amino acids in length.

7

8 Preferably, the linker of the first and / or second  
9 construct polypeptide is up to 60 amino acids.

10

11 Thus the above assay can be used to select compounds  
12 capable of triggering, stabilising or destabilising  
13 peptide to peptide interactions.

14

15 As will be apparent, the assay of the present  
16 invention can be applied in a format appropriate for  
17 large scale screening, for example, combinatorial  
18 technologies can be employed to construct  
19 combinatorial libraries of small molecules or  
20 peptides to test as modulating agents.

21

22 Preferably, structural information on the peptide to  
23 peptide interaction to be modulated is obtained by  
24 testing different agents to determine if they are  
25 modulating agents.

26

27 For example, each of the interacting pair can be  
28 expressed and purified and then allowed to interact  
29 in suitable in vitro conditions. Optionally the  
30 interacting peptides can be stabilised by  
31 crosslinking or other techniques. The interacting  
32 complex can be studied using various biophysical

1 techniques such as X-ray crystallography, NMR, or  
2 mass spectrometry. In addition, information  
3 concerning the interaction can be derived through  
4 mutagenesis experiments for example alanine scanning,  
5 or altering the charged amino acids or hydrophobic  
6 residues on the exposed surface of the bait or prey  
7 peptide being tested.

8

9 Based on the structural information obtained, the  
10 structural relationships between the interacting  
11 peptides as well as between the modulating compound  
12 and the interacting peptides can be elucidated.  
13 Further, the three dimensional structure of the  
14 interacting moieties and / or that of the modulating  
15 compound can provide information to determine  
16 suitable lead compounds able to modulate  
17 interaction, which medicinal chemists can use to  
18 design analog compounds having similar moieties and  
19 structures.

20

21 In a tenth aspect, the invention provides compounds  
22 obtainable by an assay of the invention, for example  
23 small molecules, peptides or nucleic acids which  
24 interact with the peptides being tested and modulate  
25 the formation of a peptide complex.

26

27 Modulator compounds obtained accordingly to the  
28 method of invention may be prepared as a  
29 pharmaceutical preparation or composition.  
30 Such preparations will comprise the modulating  
31 compound and a suitable carrier, diluent or  
32 excipient. These preparations may be administered

31

1 by a variety of routes, for example, oral, buccal,  
2 topical, intramuscular, intravenous, subcutaneous or  
3 the like..

4  
5 According to an eleventh aspect of the present  
6 invention there is provided a method of  
7 manufacturing a composition or preparation  
8 comprising:

9  
10 performing an assay for determining whether a  
11 candidate agent modulates peptide to peptide  
12 interactions as described above; and  
13  
14 formulating said agent into a composition.

15  
16 Also provided are nucleic acid constructs for use in  
17 the invention.

18  
19 Accordingly, in a twelfth aspect, there is provided  
20 a nucleic acid construct encoding a fragment of a  
21 fluorescent protein, a peptide and a linker portion  
22 of at least 15 amino acid residues interposed  
23 between said fragment and said peptide, wherein said  
24 fragment of fluorescent protein is capable of  
25 functional association with a complementary fragment  
26 of fluorescent protein such that on functional  
27 association of said fragments fluorescence is  
28 enabled..

29  
30 Preferably the first and / or second construct  
31 comprises a linker portion which encodes between 15  
32 to 100 amino acid residues.

1  
2 Preferably the linker is comprised of substantially  
3 hydrophillic amino-acid residues.

4  
5 More preferably the linker is comprised of multiples  
6 of a pentapeptide sequence such as glycyl-glycyl-  
7 glycyl-glycyl-serine.

8

9 More preferably the linker portion encodes greater  
10 than 20 amino acids, more preferably greater than 25  
11 amino acids, more preferably greater than 30 amino  
12 acids, more preferably greater than 35 amino acids,  
13 even more preferably greater than 40 amino acids,  
14 even more preferably greater than 50 amino acids and  
15 yet more preferably greater than 55 amino acids in  
16 length.

17

18 According to a thirteenth aspect of the invention  
19 there is provided an expression vector comprising at  
20 least one construct encoding a fragment of a  
21 fluorescent protein, a peptide and a linker portion  
22 of at least 15 amino acid residues interposed  
23 between said fragment and said peptide, wherein said  
24 fragment of fluorescent protein is capable of  
25 functional association with a complementary fragment  
26 of fluorescent protein such that on functional  
27 association of said fragments fluorescence is  
28 enabled operably linked to at least one regulatory  
29 sequence for the expression of the construct.

30

31 The vector can be introduced into the cell using any  
32 known techniques such as calcium phosphate

1 precipitation, lipofection, electroporation and the  
2 like.

3

4 Where two vectors are provided, and each vector  
5 encodes a different construct, for example a bait  
6 construct and a prey construct, the vectors can be  
7 transfected into the same cell or alternatively into  
8 two different cells which are subsequently fused  
9 together by cell fusion or other suitable  
10 techniques.

11

12 In a fourteenth aspect of the invention there is  
13 provided a cell transformed with a vector comprising  
14 at least one construct encoding a fragment of a  
15 fluorescent protein, a peptide and a linker portion  
16 of at least 15 amino acid residues interposed  
17 between said fragment and said peptide, wherein said  
18 fragment of fluorescent protein is capable of  
19 functional association with a complementary fragment  
20 of fluorescent protein such that on functional  
21 association of said fragments fluorescence is  
22 enabled operably linked to at least one regulatory  
23 sequence for the expression of the construct.

24

25 Cells which may be transformed include eukaryotic  
26 cells, such as yeast, insect, plant, mammalian,  
27 primate and human cells. Mammalian cells may be  
28 primary cells or transformed cells, including tumour  
29 cells. The system is not restricted to intracellular  
30 (single cell) interactions. In multicellular  
31 organisms amenable to genetic manipulation, a  
32 protein-hapto-GFP construct could be released from

1 one cell or organ and be recognised by another  
2 protein-(receptor)-haptoGFP fusion to indicate  
3 localisation of filled receptors by the resultant  
4 fluorescent signal.

5

6 In cell free systems such additional proteins as  
7 required for expression may be included, for  
8 example, by being provided by expression from  
9 suitable recombinant expression vectors.

10

11 In addition, there is provided in a fifteenth aspect  
12 of the invention a polypeptide encoded by a  
13 construct encoding a fragment of a fluorescent  
14 protein, a peptide and a linker portion of at least  
15 15 amino acid residues interposed between said  
16 fragment and said peptide, wherein said fragment of  
17 fluorescent protein is capable of functional  
18 association with a complementary fragment of  
19 fluorescent protein such that on functional  
20 association of said fragments fluorescence is  
21 enabled.

22

23 In a sixteenth aspect of the invention there is  
24 provided a library of polypeptides as encoded by  
25 constructs according to the fifteenth aspect of the  
26 invention.

27

28 Preferably the polypeptides of the library comprise  
29 a linker portion which encodes between 15 to 100  
30 amino acid residues.

31

1 Preferably the polypeptides of the library comprise  
2 a linker of substantially hydrophillic amino-acid  
3 residues.

4

5 More preferably the linker is comprised of multiples  
6 of a pentapeptide sequence such as glycyl-glycyl-  
7 glycyl-glycyl-serine.

8

9 More preferably the linker portion is greater than  
10 20 amino acids, more preferably greater than 25  
11 amino acids, more preferably greater than 30 amino  
12 acids, more preferably greater than 35 amino acids,  
13 even more preferably greater than 40 amino acids,  
14 even more preferably greater than 50 amino acids and  
15 yet more preferably greater than 55 amino acids in  
16 length.

17

18 Preferably, the linker comprises up to 60 amino  
19 acids.

20

21 Preferably the first and / or second linker of the  
22 vector, or polypeptide can comprises between 15 to  
23 100 amino acid residues.

24

25 Preferably the first and / or second linker is  
26 comprised of substantially hydrophillic amino-acid  
27 residues.

28

29 More preferably the first and / or second linker is  
30 comprised of multiples of a pentapeptide sequence  
31 such as glycyl-glycyl-glycyl-glycyl-serine.

32

1 More preferably the first and / or second linker  
2 portion encodes or comprises greater than 20 amino  
3 acids, more preferably greater than 25 amino acids,  
4 more preferably greater than 30 amino acids, more  
5 preferably greater than 35 amino acids, even more  
6 preferably greater than 40 amino acids, even more  
7 preferably greater than 50 amino acids and yet more  
8 preferably greater than 55 amino acids in length.

9  
10 According to a seventeenth aspect of the present  
11 invention there is provided a kit comprising at  
12 least one pair of constructs according to the first  
13 aspect of the invention and means to express the  
14 constructs.

15  
16 The kit may further include test agents, which may  
17 enhance or inhibit peptide to peptide interaction.

18  
19 In another embodiment the kit includes cell lines in  
20 which the vector of the third aspect can be  
21 expressed.

22  
23 Alternatively the kit can comprise at least one  
24 polypeptide of the fifth aspect of the invention and  
25 means for introducing the polypeptide into a cell.

26  
27 Additionally, the kit can include instructions for  
28 using the kit to practise the present invention.  
29 The instructions should be in writing in a tangible  
30 form or stored in an electronically retrievable  
31 form.

32

1     Brief description of the figures

2

3     The present invention will now be described with  
4     reference to the following non-limiting examples and  
5     with reference to the figures, wherein:

6

7             Figure 1a is a ribbon diagram of EGFP annotated  
8             with split point sites;

9

10            Figure 1b is an illustration of the split  
11            points and the related sequences surrounding  
12            these split points of EGFP;

13

14            Figure 2 is a representation of a hapto-EGFP  
15            with a 26 residue linker between the  
16            fluorogenic fragments and the bait and prey  
17            proteins respectively;

18

19            Figure 3 is a graph of the fluorescence  
20            produced by the association of fragments joined  
21            to linkers of different lengths, (A) Cells  
22            cotransfected with pN157(6)zip and pzip(4)C158  
23            in which a functional leucine zippers mediate  
24            the association of haptoEGFP1-157 and  
25            haptoEGFP158-238 to generate fluorescence, (B)  
26            Negative control cotransfection using pN157(6)  
27            and p(4)C158 which lack sequences encoding the  
28            leucine zippers and as such fail to generate  
29            fluorescence, (D) Cells cotransfected with  
30            pN172(6)zip and pzip(4)C173 in which a  
31            functional leucine zipper mediated association  
32            of haptoEGFP1-172 and haptoEGFP173-238 occurs

1 to generate fluorescence which is of greater  
2 intensity to that observed with the 157/158  
3 split point (E) Negative control  
4 cotransfection using pN172(6) and p(4)C173  
5 which lack sequences encoding the leucine  
6 zippers and as such fail to generate  
7 fluorescence, (C and F) Confocal images of  
8 cotransfected cells from (A) and (D) showing  
9 the intracellular localisation of fluorescence.  
10 Vero cells were cotransfected with plasmids  
11 encoding linkers ranging in length from 4 to 26  
12 amino acids and UV images were collected at 24  
13 hours post-transfection using identical  
14 exposure times, (G) pN157(6)zip and  
15 pzip(4)C158 (H) pN157(16)zip and pzip(14)C158  
16 (I) pN157(26)zip and pzip(24)C158 (J) pN157(6)zip  
17 and pzip(4)C158 (K) pN157(16)zip and pzip(14)C158  
18 and pzip(24)C158 (L) a negative untransfected  
19 control illustrates the background fluorescence  
20 level, Italicised figures in brackets indicate  
21 the length of the hydrophilic linker;

22  
23 Figure 4 shows the importance of being able to  
24 fuse the interacting peptide to either the N,  
25 N', C or C' of the fluorescent fragment.

26  
27 Structural studies of GFP have revealed that the  
28 protein exists as a compact cylindrical structure,  
29 with eleven beta-sheet strands forming the walls of  
30 the cylinder, the N and C termini being at close  
31 proximity at the base of the structure. Sections of  
32 alpha-helix form caps on the end of the cylinders

1 and an irregular alpha-helical segment also provides  
2 a scaffold for the fluorophore which is located in  
3 the geometric center of the cylinder. This folding  
4 motif, with beta-sheet outside and helix inside is  
5 known as beta-can.

6  
7 The inventors have shown that fluorescence can be  
8 generated following functional association of two  
9 separate fragments of GFP molecules (haptoGFPs) when  
10 driven by the interactions of a pair of proteins  
11 fused both to the new C' and N' termini of each  
12 haptoGFP and also to the existing termini.

13  
14 Functional association of fragments of fluorescent  
15 proteins, brought together by the interaction of  
16 peptides fused to the fragments, to screen for  
17 protein to protein interactions requires that the  
18 fragments reliably functionally associate only after  
19 interaction of the fused peptides.

20  
21 Reliable functional association has to date not been  
22 obtainable due to the possibility of steric  
23 hindrance and steric constraints on the functional  
24 association of haptoGFPs when bulky proteins are  
25 associated to the GFP fragments.

26  
27 - To overcome problems of steric hindrance, linker  
28 regions of at least 15 residues are provided between  
29 the peptide being tested for interaction and the  
30 associated fluorogenic fragment. This provides the  
31 peptide with considerable flexibility relative to  
32 the fluorogenic fragment to bind to another peptide

1 being tested while still enabling the fluorogenic  
2 fragments to complement each other and cause  
3 detectable fluorescence to be generated.

4  
5 To prepare GFP fragments, which are capable of  
6 functional association, split points were generated  
7 at various points along the 239 residue length of  
8 the GFP protein, resulting in the generation of new  
9 C' and N' termini which, in three dimensions, are  
10 located at the top and at the base of the beta-can  
11 structure.

12  
13 Split points were introduced based on a structure  
14 driven approach between hydrophilic residues. The  
15 eleven strands of the beta structure making up the  
16 beta-can topology of EGFP are characterised by  
17 forming three instances of a tripartite antiparallel  
18 sheet motif joined edge to edge around the periphery  
19 of the 'can', with the remaining two beta strands  
20 completing the cylindrical structure. The most  
21 successful split points obtained to date occur in  
22 the third tripartite motif between hydrophilic  
23 residues allowing adjacent hydrophobic side chains  
24 to promote refolding of the haptogFPs.

25  
26 As shown in the non exhaustive list of Table 1 a  
27 number of split points were identified using the  
28 above approach. It would appear that each split  
29 point in Table 1 is simply one example of a range of  
30 potentially useful split points, the range being  
31 shown in parentheses of Table 1.

32

1 Table 1

Split point Number	Residue position in EGFP	Possible range
1	23/24	(23-25)
2	38/39	(36-41)
3	50/51	(48-54)
4	76/77	(75-91)
5	89/90	(75-90)
6	102/103	(101-103)
7	116/117	(115-118)
8	132/133	(129-143)
9	142/143	(129-143)
10	157/158	(155-160)
11	172/173	(171-175)
12	190/191	(187-199)
13	211/212	(207-218)
14	214/215	(207-218)

2  
3  
4 To extend the versatility of the hapto-EGFP method,  
5 constructs were created where instead of using C'  
6 and N' for the attachment of heterologous proteins,  
7 the endogenous termini, N or C together with one of  
8 the new N' or C' termini were used. Using this  
9 technique the bait and prey peptides can be added  
10 such that they are orientated to the associated  
11 fluorogenic fragments in the same direction as each  
12 other, for example both attached to bottom of the  $\beta$ -  
13 can structure of GFP or in the opposite direction,  
14 for example the bait peptide is attached to the

1 bottom of the  $\beta$ -can structure of GFP, while the prey  
2 protein is attached to the top of the  $\beta$ -can  
3 structure of GFP. As will be understood by those  
4 skilled in the art, and as shown in figures 4 A & B,  
5 as peptides interact with each other in a particular  
6 orientation, then the direction of the linkage of  
7 the peptide to the N, N', C or C' end of the  
8 fluorogenic fragment becomes important in certain  
9 circumstances so as to allow the fluorescent protein  
10 fragments to functionally interact following  
11 interaction of the peptides.

12

13 Thus, to minimise interference with the refolding  
14 and association of the two hapto-EGFPs during  
15 assembly, it would appear that the most versatile  
16 split points may occur at the bottom of the  $\beta$ -can.  
17 These effects may be minimised by the use of longer  
18 linkers to accommodate adverse topology (Figure 4C).

19

#### 20 Example 1

21

22 As shown in figures 2 and 3, hapto-EGFP with a 26-  
23 residue linker between the fluorogenic fragments and  
24 the bait and prey proteins respectively were  
25 produced without loss of fluorescence. These  
26 linkers may be lengthened using overlapping  
27 oligonucleotides encoding repeating (GGGS)<sub>x</sub> units.  
28 This was achieved by using unique Sac I and BamHI  
29 restriction sites present in the core expression  
30 vectors pN<sup>EGFP</sup>(Sac)zip and pzip(Bam)C<sup>EGFP</sup>.

31

43

1 To test whether it was possible to obtain  
2 fluorescence when endogenous N or C termini and a  
3 new N' or C' terminus are used to attach heterologous  
4 proteins the fusion (F) and haemagglutinin (H)  
5 membrane proteins of measles virus (MV) were used.  
6

7 Measles virus (MV) infection is mediated by a  
8 complex of two viral envelope proteins,  
9 haemagglutinin (H) glycoprotein and fusion (F)  
10 glycoprotein that bind to each other and then  
11 complex with surface receptors to aid the fusion of  
12 the virus with the plasma membrane. The H  
13 glycoprotein is dimerised in the endoplasmic  
14 reticulum and is thought to exist on the cell  
15 surface as a tetramer (dimer of dimers). The fusion  
16 (F) glycoprotein, is synthesised as an inactive  
17 precursor ( $F_0$ ) which is a highly conserved type I  
18 transmembrane glycoprotein of about 60kDa, which is  
19 cleaved by furin in the trans-golgi to yield the  
20 41kDa ( $f_1$ ) and the 18kDa ( $f_2$ ) disulphide-linked  
21 activated F-protein. Infection of the measles virus  
22 is dependent on the interaction of the F/H complex  
23 with cell surface receptors.  
24

25 A pair of constructs was generated which encoded the  
26 H glycoprotein fused at its N terminus to either the  
27 C' terminal residue of hapto-EGFP<sup>1-157</sup> ( $N^{1/157}$ ) in the  
28 first member, or to the natural C terminal residue  
29 of the complimentary hapto-EGFP<sup>158-239</sup> ( $C_{158/239}$ ) in  
30 the second member of the pair. Each construct  
31 includes an encoded linker between these two  
32 proteins.

13 Vero cells (African green monkey kidney-derived cell  
14 line) were transiently transfected with pN<sup>1/157</sup>(16)MV-  
15 H and pMV-F(14)C<sup>158/238</sup> constructs, the proteins  
16 expressed and phase contrast microscopy used to  
17 determine whether the modified glycoproteins  
18 retained their fusogenicity.

25 As cells transiently transfected with both F and H  
26 expression plasmids form syncytia in the absence of  
27 viral replication, the formation of syncytia can be  
28 used to assay for successful transfection of both  
29 plasmids.

0086724 21-Nov-03 06:03

45

1 and confocal microscopy were used to examine the  
2 fluorescence so as to verify that association  
3 between H protein oligomers and F proteins had taken  
4 place. Confocal microscopy and image reconstruction  
5 were also used to determine the intracellular  
6 localisation of H protein oligomers during formation  
7 of the fusion complex.

8  
9 Using the above vectors the intracellular  
10 association of F and H proteins and their  
11 trafficking from the endoplasmic reticulum (ER) to  
12 the plasma membrane was tracked. Further, membrane  
13 receptor proteins which interact with the H protein  
14 could be identified as could cytoplasmic proteins  
15 which interact with known MV receptors and which may  
16 therefore initiate downstream signalling events.

17  
18 Example 2

19  
20 The above constructs could also be incorporated into  
21 a recombinant measles viral genome and the  
22 experiments repeated to determine if the above  
23 constructs could be used in in vivo viral studies,

24  
25 The type-I F glycoprotein is proposed to form  
26 trimers.

27  
28 In this example two split points could be introduced  
29 into the EGFP. The constructs pMV-F(16)N<sup>1/157</sup>, pMV-  
30 F(14)M<sup>158/190</sup> and pMV-F(14)C<sup>191/239</sup> could be generated.

31

1 The method could then be adapted to screen for and  
2 identify virus receptors.

3

4 This could be tested with MV and applied to the  
5 closely related mumps virus (MuV).

6

7 Example 3

8

9 Fusion of oligonucleotides encoding hapto-EGFP  
10 sequences to members of a cDNA library.

11

12 Firstly, the sequence encoding the hapto-EGFP may be  
13 fused to the 5' end of the library due to the  
14 presence of downstream stop codons in the cDNA.

15

16 Secondly, constructs are required to be generated  
17 for all three reading frames to ensure that one is  
18 in the correct reading frame.

19

20 Thirdly, the cDNA sequences are required to be  
21 obtained from a source which permits directional  
22 cloning into restriction sites which are extremely  
23 rare in mammalian DNA. Such sequences are to be  
24 found in the *Large-Insert cDNA library* (Clontech).

25

26 A core panning vector could be engineered from  
27 existing plasmids to contain a CMV promoter, an  
28 initiation codon and sequences encoding a hapto-EGFP  
29 and an intervening linker, an *Sfi* IA site and an *Sfi*  
30 IB site, a stop codon and an SV40 polyadenylation  
31 signal. Two additional screening vectors could be  
32 generated to include one and two extra nucleotides

1 between the linker and the *Sfi* IA site to correct  
2 the reading frame. cDNA fragments, flanked with *Sfi*  
3 IA and *Sfi* IB sites obtained from the library could  
4 be cloned downstream of the optimised hapto-EGFP  
5 linker constructs. The hapto-EGFP library could then  
6 be transfected into CHO cells and a mixed population  
7 of cells selected using G418 and passaged to  
8 confluency. These cells could then be transfected  
9 with CD46-haptoEGFP or the equivalent SLAM plasmid.

10

11 Where interaction between the peptides being  
12 screened occurs, fluorescence is generated.

13

14 Any cells which fluoresce can then be isolated by  
15 fluorescent laser microdissection and single cell  
16 RT-PCR performed to identify mRNA which encodes  
17 peptides which interact with the cytoplasmic tails  
18 of the receptor molecules.

19

20 Although the invention has been particularly shown  
21 and described with reference to particular examples,  
22 it will be understood by those skilled in the art  
23 that various changes in the form and details may be  
24 made therein without departing from the scope of the  
25 present invention.

26

27

Figure 1

A

**GFP fold:** The ribbon diagram to the left is coloured similarly to the cartoon on the right.  $\beta$ -sheets are indicated by arrows,  $\alpha$ -helices by cylinders. Numbers within these symbols refer to sequence positions in EGFP (numbered according to the crystallographic structure - accession: 1emb). In the cartoon, connecting loops are shown by lines. Potential split points are starred and numbered sequentially from the N-terminus, (see B below for precise definitions). The fluorophore is represented by a green circle.

B

Possible split points in EGFP considered for hapto formation.

No.	Position	Top/ Bottom	>-----Sequence----->

Figure 2

# Library search and proximity measurement

Schematic for protein to protein interaction searches by library interrogation. The two proteins in question are designated 'Bait' and 'W'. Two libraries are generated (I and II), one series of constructs (here designated T...Z, library I, >10,000 members) encodes a hapto-EGFP followed by a DNA sequence encoding a 60 residue linker attached to the 5'-end of a cDNA library, which contains the gene encoding the 'prey', "W" here. The second series of constructs (a...e here, library II, <20 members) encodes the complementary hapto-EGFP followed by a degenerate linker DNA sequence and the 'bait' gene. The individual components of the system are colour coded: blue - 'Bait'/Prey'; pink - Linker; green - hapto-EGFP. All arrows indicate the direction of the polypeptide backbone (N->C)

**A. 'Prey' identification:** co-transfection with the 'prey' library (I) and construct 'e' (long linker - preferably 60 amino acid residues) from the 'bait' library (II) will generate fluorescent cells when the recipient cell receives a vector from library (I) bearing the 'W' gene (in this case) and a second vector bearing the 'e' bait construct. Clonal expansion of these fluorescent cells allows identification of gene 'W'.

**B. Proximity measurement:** The clone(s) from step A are co-transfected with the 'bait' library (II). In this case cells showing fluorescence synthesise interacting proteins with a sufficiently long linker to allow productive complementary hapto-GFP interaction ('d' or 'e' in this case), as shown to the left of the diagram. The hollow blue arrows in the right hand part of the diagram are intended to indicate that the interaction of the gene products with these two constructs will generate fluorescence, while other interactions between the product of gene 'W' and the bait protein will not give rise to fluorescent cells due to insufficient length of linker.
